- ► Type II Error β

- ► Rejection Region
- ▶ Type I Error α
- ▶ Type II Error β
- ▶ power=1 $-\beta$

- Rejection Region
- ▶ Type I Error α
- ▶ Type II Error β
- ▶ power=1 $-\beta$
- In a lot of applications, people like to talk about power instead of Type II Error β .

Criteria

- A good test will be aimed to make two types of errors, both α and β , as small as possible.
- Unfortunately, there is no rejection region that will simultaneously make both α and β small once the test statistic and sample size are fixed. Thus, a region must be chosen to effect a compromise between α and β .
- Because of the suggested guidelines for specifying and . A type I error is usually more serious than a type II error (we don't want to reject the null easily).
- In practice, people specify to the largest value that α can be tolerated and find a rejection region having that value of α . The resulting value of α is often referred to as the significance level of the test (0.1, 0.05, 0.01). The corresponding test procedure is called an α level test. The previous example was an exact 0.05-level test.

Hypothesis Testing for a Population Mean

- In this section, the null hypothesis is about a population mean $H_0: \mu = \mu_0$ and there are there possible Alternative Hypothesis $H_a: \mu > \mu_0$ or $H_a: \mu < \mu_0$ or $H_a: \mu \neq \mu_0$.
- ► We will discuss three cases which parallel our discussion about Confidence Interval for a Population Mean.
- ▶ Case I: Normal Distribution and Known σ (z Test)
 - ▶ Case II: General Distribution, Unknown σ but Large Sample (z Test)
 - ▶ Case III: Normal Distribution and Unknown σ (t Test)

Under the null hypothesis, the test statistic

$$Z = \frac{\bar{X} - \mu_0}{\sigma \sqrt{n}}$$

follow a standard normal distribution.

Under the null hypothesis, the test statistic

$$Z = \frac{\bar{X} - \mu_0}{\sigma \sqrt{n}}$$

follow a standard normal distribution.

If the Alternative Hypo is $H_a: \mu > \mu_0$, then the Rejection Region is something like $\{z \geq z_0\}$.

Under the null hypothesis, the test statistic

$$Z = \frac{\bar{X} - \mu_0}{\sigma \sqrt{n}}$$

follow a standard normal distribution.

- If the Alternative Hypo is H_a : $\mu > \mu_0$, then the Rejection Region is something like $\{z \geq z_0\}$.
- ▶ z_0 is determined by the level of the test α , if we set z_0 as z critical value z_{α} then

$$P(\text{type I error}) = P(H_0 \text{ is rejected when } H_0 \text{ is true})$$

= $P(Z > z_{\alpha} \text{ when } Z \sim N(0, 1)) = \alpha$

- ▶ We can also compute Type II Error β and sample size n. Still we consider the upper-tailed test as a demonstration.
- ▶ Type II Error β will be a function of any particular number μ' that is larger than the null value μ_0 .

$$\beta(\mu') = P(Z < z_{\alpha} \text{ when } \mu = \mu')$$

$$= P(\frac{\bar{X} - \mu_0}{\sigma \sqrt{n}} < z_{\alpha} \text{ when } \mu = \mu')$$

$$= P(\frac{\bar{X} - \mu'}{\sigma \sqrt{n}} < z_{\alpha} + \frac{\mu_0 - \mu'}{\sigma \sqrt{n}} \text{ when } \mu = \mu')$$

$$= \Phi(z_{\alpha} + \frac{\mu_0 - \mu'}{\sigma \sqrt{n}}) \le 1 - \alpha$$

- Φ () is the CDF of standard normal.
- What is the power of the test?

```
Null hypothesis: H_0: \mu = \mu_0

Test statistic value: z = \frac{\overline{x} - \mu_0}{\sigma/\sqrt{n}}

Alternative Hypothesis

Rejection Region for Level \alpha Test

H_a: \mu > \mu_0

Z \geq Z_\alpha (upper-tailed test)

Z \leq -Z_\alpha (lower-tailed test)

Z \leq -Z_\alpha (lower-tailed test)

Z \leq -Z_\alpha (in the statistic value: Z \leq -Z_\alpha (lower-tailed test)

Z \leq -Z_\alpha (lower-tailed test)

Z \leq -Z_\alpha (in the statistic value: Z \leq -Z_\alpha (lower-tailed test)

Z \leq -Z_\alpha (lower-tailed test)
```

```
Null hypothesis: H_0: \mu = \mu_0

Test statistic value: z = \frac{\overline{x} - \mu_0}{\sigma/\sqrt{n}}

Alternative Hypothesis

Rejection Region for Level \alpha Test

H_a: \mu > \mu_0

z \ge z_\alpha (upper-tailed test)

H_a: \mu < \mu_0

z \le -z_\alpha (lower-tailed test)

z \le -z_\alpha (lower-tailed test)

z \le -z_\alpha (two-tailed test)

z \le -z_\alpha (two-tailed test)
```

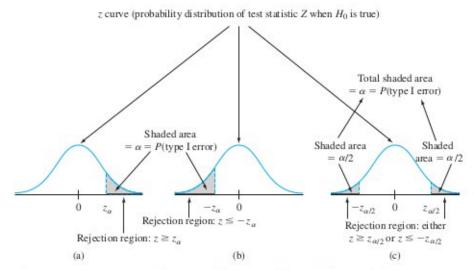

Figure 8.2 Rejection regions for z tests: (a) upper-tailed test; (b) lower-tailed test; (c) two-tailed test

- ▶ We can even derive the formula for type II error β .
- ▶ For a given True Value μ' , Type I Error level α and Type II Error β , we can determined the sample size n that we need with

$$\Phi(\mathbf{z}_{\alpha} + \frac{\mu_0 - \mu'}{\sigma \sqrt{n}}) = \beta$$

Thus

$$-z_{\beta} = z_{\alpha} + \frac{\mu_0 - \mu'}{\sigma \sqrt{n}}$$

Alternative Hypothesis Type II Error Probability $\beta(\mu')$ for a Level α Test

$$\begin{split} \mathbf{H}_{\mathrm{a}} &: \quad \mu > \mu_0 \\ \mathbf{H}_{\mathrm{a}} &: \quad \mu < \mu_0 \\ \mathbf{H}_{\mathrm{a}} &: \quad \mu < \mu_0 \\ \mathbf{H}_{\mathrm{a}} &: \quad \mu < \mu_0 \\ \mathbf{H}_{\mathrm{a}} &: \quad \mu \neq \mu_0 \\ \mathbf{H}_{\mathrm{a}} &: \quad$$

where $\Phi(z)$ = the standard normal cdf.

The sample size n for which a level α test also has $\beta(\mu')=\beta$ at the alternative value μ' is

$$\mathbf{n} = \begin{cases} \left[\frac{\sigma(\mathbf{z}_{\alpha} + \mathbf{z}_{\beta})}{\mu_0 - \mu'} \right]^2 & \text{for a one-tailed} \\ \left[\frac{\sigma(\mathbf{z}_{\alpha/2} + \mathbf{z}_{\beta})}{\mu_0 - \mu'} \right]^2 & \text{for a two-tailed test} \\ \left[\frac{\sigma(\mathbf{z}_{\alpha/2} + \mathbf{z}_{\beta})}{\mu_0 - \mu'} \right]^2 & \text{for a two-tailed test} \\ & \text{(an approximate solution)} \end{cases}$$

Example

Let μ denote the true average tread life of a certain type of tire. Consider testing H $_0$: $\mu=30{,}000$ versus H $_a$: $\mu>30{,}000$ based on a sample of size n = 16 from a normal population distribution with $\sigma=1500$. A test with $\alpha=.01$ requires $z_{\alpha}=z_{.01}=2.33$. The probability of making a type II error when $\mu=31{,}000$ is

$$\beta(31,000) = \Phi\left(2.33 + \frac{30,000 - 31,000}{1500/\sqrt{16}}\right) = \Phi(-.34) = .3669$$

Since $z_1=1.28$, the requirement that the level .01 test also have $\beta(31,000)=.1$ necessitates

$$n = \left[\frac{1500(2.33 + 1.28)}{30,000 - 31,000}\right]^2 = (-5.42)^2 = 29.32$$

The sample size must be an integer, so n = 30 tires should be used.

Case II: General Distribution, Unknown σ but Large Sample (z Test)

 As we discussed in Confidence Interval, under the null hypothesis, the test statistic

$$Z = \frac{\bar{X} - \mu_0}{\hat{\sigma}\sqrt{n}}$$

approximately follow a standard normal distribution.

- ▶ The rule of thumb is n > 40.
- ▶ All the procedure, e.g., Test Statistic, Rejection Region and formula for β and sample size, are the same except for substituting σ with its estimator $\hat{\sigma}$.

Under the null hypothesis, the test statistic

$$T = \frac{\bar{X} - \mu_0}{\hat{\sigma}\sqrt{n}}$$

follows a t distribution with degrees of freedom n-1

Under the null hypothesis, the test statistic

$$T = \frac{\bar{X} - \mu_0}{\hat{\sigma}\sqrt{n}}$$

follows a t distribution with degrees of freedom n-1

▶ Test Procedure

The One-Sample t Test Null hypothesis: H_0 : $\mu = \mu_0$ Test statistic value: $t = \frac{\overline{x} - \mu_0}{s/\sqrt{n}}$ Alternative Hypothesis Rejection Region for a Level α Test $t \geq t_{\alpha,n-1}$ (upper-tailed) $t \leq -t_{\alpha,n-1}$ (lower-tailed) $t \leq -t_{\alpha,n-1}$ (lower-tailed) either $t \geq t_{\alpha,2,n-1}$ or $t \leq -t_{\alpha,2,n-1}$ (two-tailed)

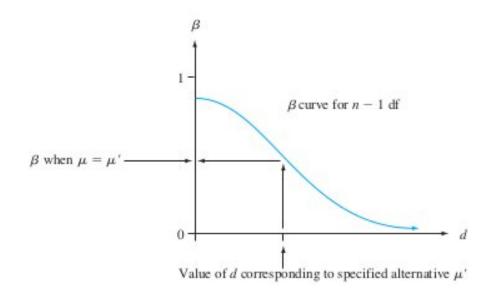

▶ The calculation of Type II Error β is much more difficult than z Test.

$$\beta(\mu') = P(T < t_{\alpha,n-1} \text{ when } \mu = \mu' \text{ rather than } \mu_0)$$

▶ The calculation of Type II Error β is much more difficult than z Test.

$$\beta(\mu') = P(T < t_{\alpha,n-1} \text{ when } \mu = \mu' \text{ rather than } \mu_0)$$

▶ A typical β curve

Population proportion

- Let *p* denote the proportion of individuals or objects in a population who possess a specified property (probability of success). In order to make inference about p, naturally we would look at the sample proportion, which is X/n. X is the number of S's in the sample. In practice, X normally should follow a hyper-geometric distribution, which can often be approximated by a binomial distribution, and when n is large, it can further be approximated by a normal distribution.
- We first consider large sample tests.

Large-sample tests

Thanks to the Central Limit Theorem, we have

$$Z = \frac{\hat{p} - p_0}{\sqrt{p_0(1 - p_0)/n}} \sim N(0, 1)$$

under the null hypothesis.

- Thus the rejection region is determined by
- 1. H_a : $p > p_0$: $Z > z_\alpha$
- 2. H_a : $p < p_0$: $Z < -z_\alpha$
- 3. H_a : $p \neq p_0$: $Z > z_{\alpha/2}$ or $Z_0 < -z_{\alpha/2}$
- The test procedures are valid provided that $np_0 \ge 10$ and $n(1-p_0) \ge 10$.

Example

Ex. (Defective rate cont.) A factory claims that less than 10% of the components they produce are defective. A consumer group is skeptical of the claim and checks a random sample of 300 components and finds that 39 are defective. Is there evidence that 10% of all components made at the factory are defective?

$$H_0: p = 0.10$$
 $H_a: p > 0.10$

$$\hat{p} = \frac{39}{300} = 0.13$$
 $Z = \frac{0.13 - 0.1}{\sqrt{0.1(1 - 0.1)/300}} = 1.72$

 $z_{0.05}$ = 1.645. Z > $z_{0.05}$, thus we would reject H_0 at level α =0.05.

Type II error

• We consider the upper tail test with rejection region $Z > z_{\alpha}$ and try to calculate the type II error associated with this test.

$$\beta(p') = P(H_0 \text{ is not rejected when } p = p')$$

$$= P\left(\frac{\hat{p} - p_0}{\sqrt{p_0(1 - p_0)/n}} \le z_\alpha | p = p'\right)$$

$$= P\left(\frac{\hat{p} - p'}{\sqrt{p_0(1 - p_0)/n}} \le z_\alpha + \frac{p_0 - p'}{\sqrt{p_0(1 - p_0)/n}} | p = p'\right)$$

$$= P\left(\frac{\hat{p} - p'}{\sqrt{p'(1 - p')/n}} \le \frac{z_\alpha \sqrt{p_0(1 - p_0)/n}}{\sqrt{p'(1 - p')/n}} + \frac{(p_0 - p')}{\sqrt{p'(1 - p')/n}} | p = p'\right)$$

$$= \Phi\left(\frac{p_0 - p' + z_\alpha \sqrt{p_0(1 - p_0)/n}}{\sqrt{p'(1 - p')/n}}\right)$$

Formulas for different alternatives can be derived in a similar way. (Book p.308)

Determining sample size

• If we specify a particular alternative p' and specify a β value that can be tolerated (e.g. 0.1). Then from

$$\beta = \Phi\left(\frac{p_0 - p' + z_\alpha \sqrt{p_0(1 - p_0)/n}}{\sqrt{p'(1 - p')/n}}\right) \Longrightarrow -z_\beta = \frac{p_0 - p' + z_\alpha \sqrt{p_0(1 - p_0)/n}}{\sqrt{p'(1 - p')/n}}$$

 Therefore, in order to achieve the specified type I and type II error, one has to have a sample size of at least

$$n = \left(\frac{z_{\alpha}\sqrt{p_0(1-p_0)} + z_{\beta}\sqrt{p'(1-p')}}{p' - p_0}\right)^2$$

- For two sided test, we have to change z_{α} to $z_{\alpha/2}$ in the above formula.
- Difference between the sample size calculation formula in chapter 7 and the one above.

Example

Ex. A package-delivery service advertises that at least 90% of all packages brought to its office by 9 a.m. for delivery in the same city are delivered by noon that day. Let p denote the true proportion of such packages that are delivered as advertised and consider the hypothesis H_0 : p = 0.9 versus H_a : p < 0.9. If only 80% of the packages are delivered, how likely is it that a level .01 test based on n=225 packages will detect such departure from H_0 ? What should the sample size be to ensure that $\beta(0.8) = 0.01$? With $\alpha = .01$, $p_0 = .9$, p' = .8, and n = 225.

Type II error:
$$\beta(p') = 1 - \Phi\left(\frac{p_0 - p' - z_\alpha \sqrt{p_0(1 - p_0)/n}}{\sqrt{p'(1 - p')/n}}\right)$$

$$= 1 - \Phi\left(\frac{.9 - .8 - 2.33\sqrt{(.9)(.1)/225}}{\sqrt{(.8)(.2)/225}}\right)$$

$$= 1 - \Phi(2.00) = .0228$$

Example cont.

• Using z_{01} =2.33, the sample size can then be calculated from

$$n = \left(\frac{z_{\alpha}\sqrt{p_{0}(1-p_{0})/n} + z_{\beta}\sqrt{p'(1-p')/n}}{p'-p_{0}}\right)^{2}$$
$$= \left(\frac{2.33\sqrt{(.9)(.1)} + 2.33\sqrt{(.8)(.2)}}{.8-.9}\right)^{2} \approx 266$$

• 1- β is often referred to as the power of a test. It is the probability that the test can actually detect the alternative given the alternative is true! For α -level tests, the bigger the power the better!

Small sample tests

- For testing population proportions, when the sample size is small, the normal approximation is no longer appropriate. Thus a more accurate test should be used.
- As mentioned before, the sample proportion is X/n. X is the number of S's in the sample and can be treated as a binomial random variable. Thus a rejection region can be constructed using binomial cdf/pmf.
- Can we get an exact α -level test using binomial?
